## ABSTRACT

This thesis is a design of an officer allocation model for the United States Marine Corps. It is a prototype software system that supports the modeling of various officer assignment policies. Officer allocation is the mapping of officer types to classes of billets. Assignment is the matching of a particular officer to a specific billet. This thesis examines the current officer allocation capability and proposes the design of a software system that will permit those making assignments the capability to define the type of allocation model that will best support their needs.

## **ACKNOWLEDGEMENTS**

I would like to thank Professor Bradley for all of his support and patience in working with me. I would also like to thank all of my friends that encouraged me, fed me, and prayed for me as I worked on the thesis.

## I. INTRODUCTION

### A. BACKGROUND

The primary mission of the U.S. Marine Corps is to defend the U.S. and its interests. In order to accomplish this mission, the Marine Corps established a personnel structure that organizes people into various sized combat and support units. There are approximately 190,000 marines in the Marine Corps, of which 20,000 are commissioned officers and 170,000 are enlisted. The Marine Corps has three major combat units known as Marine Amphibious Forces (MAF). There is one each on the East and West coasts, and one split between Hawaii and Japan. There is also a fourth MAF that is make up of marine reservists. Each MAF consists of a combat Division, a Force Service Support Group, and an aircraft Wing. Each of these units can be broken down again several times into their most elemental units. There are also marines stationed at bases, schools, and other posts that support the Marine Corps. Each of the different units require people with special and specific skills in order for each unit to effectively support the Marine Corps missions. Within the officer corps there are 168 such skills or Military Occupational Specialties (MOS). Each officer has a designated primary specialty and may have up to two additional specialties designated as additional MOS's (AMOS's). In addition, each officer has a designated rank or grade such as Lieutenant, Captain, Major, etc.

Each unit in the Marine Corps has a Table of Organization (T/O) that specifies how many officers (and enlisted) are required of each MOS and grade to fully man the unit. These T/O's are maintained at Headquarters Marine Corps (HQMC) in Washington, DC. The Manpower Management Officer Assignment Branch (MMOA) at HQMC is tasked with ensuring that all of the authorized officer billets in the Marine Corps are filled. There is also a similar branch that handles the enlisted, however, it will not be discussed. MMOA has two sections of officers known as monitors. Each monitor is responsible for billets with different sets of MOS's and grades. For example, one monitor may handle Artillery and Financial Management Captains and Lieutenants, while another monitor may take care of Artillery and Infantry Majors. The monitors keep track of each of their authorized officer billets and assign officers to fill those billets. Historically, about seven to eight thousand officers are assigned to

new jobs (militarily known as billets) each year. Each billet can be specifically described by the command (unit) it is at, a MOS and a grade. In making assignments the monitors consider special command needs, career patterns of the officers, staffing requirements, preferences of the individual, the population of officers, the number of officers in each MOS, the relative priority of billets and the staffing policies in effect at the time. Because all of these factors do not all agree completely, it is not always possible for the monitor to assign an officer that exactly matches the given requirements for every billet. How well an officer matches the requirements of a billet is known as the 'fit'. There are also several billets, usually at support commands, that are not restricted to just one MOS or grade. These billets, then, may be filled by one of several monitors. The filling of these billets must be coordinated between those monitors.

To aid the monitors in making their assignments, the Officer Staffing Goal Model (OSGM), a computer-based model, was developed and implemented over ten years ago. The purpose of the OSGM is to provide each monitor with an optimal staffing goal target; that is, a staffing goal with the greatest possible number of billets filled and the best possible fit for those officers. A staffing goal is a listing of each billet at each command and the description of a type of officer that can fill that billet. The OSGM does not attempt to consider special command needs, career patterns and individual Marine preferences because these change very frequently and are very difficult to model on a computer. Its output is therefore considered a target for the monitors to strive for and is used as a tool by them when making their assignments. Again, the OSGM has two objectives when creating staffing goals: to fill the largest number of billets possible and to have the best 'fit' for each billet filled. It is not normally feasible to fill all the billets that are authorized or to have the best 'fit' for every billet filled. The current OSGM takes care of this by first getting the best fill possible and then within that constraint finding the best fit attainable.

There are three inputs to the OSGM: the inventory of the current Marine Corps officer population, the listing of all authorized billets (known as the ASR), and the 'Dictionary'--a collection of data used by the OSGM to apply current Marine Corps assignment policy to the model. Using these inputs, the OSGM performs several functions in developing the staffing goal.

The first of these functions is the updating of the ASR. The ASR is generated three times a year. The ASR is a subset of the T/O. Again, the T.O is a listing of all

the personnel needed to fully complement a unit. But because of budget and manpower constraints, not every unit can be fully manned. Therefore, the ASR was established to record which billets out of the T/O are authorized. At each model run, all of the changes to the billet structures that have been approved by HQMC in the previous four months are applied to the ASR. Since the OSGM may be run more often than this and should be as up to date as possible in order to give the best possible solution, the ASR can be adjusted by the OSGM to reflect any changes in the authorized officer strengths that have occurred since the ASR file was generated, or when the authorized strength is not broken out in a manner needed by the model. The adjustments to the ASR can be increases or decreases to current authorizations, setting authorizations to specific levels, or adding new authorizations that previously did not exist. An example of the ASR is given in Figure 1.1 .

BMOS	GRADE	MCC	NO. of BILLETS
0802	03	V15	9

Figure 1.1 Authorized Strength Report (ASR).

In a similar manner the Inventory or officer population must also be kept up to date. The Inventory is reduced to reflect those first term officers who will be leaving active duty. These reductions are accomplished by randomly pulling officers of specified grades and MOS's from the Inventory before the model is run. The grades and MOS's can either be specified by major categories or by specific grade and MOS. The officer inventory can also be adjusted to show accessions or attritions for other than first term officers. Any officer type (specified by MOS, grade, experience, sex and additional MOS) can be increased, decreased or set to a given level. An example of the Inventory data is shown in Figure 1.2 .

The Dictionary is used to specify what type of officer can fill a given billet type at a command (this is known as the substitutions for a billet). Each officer is described by his primary MOS, any additional MOS's, his grade and indicators that show the officer's sex, experience level and LDO/unrestricted status. Each billet has a set of

PMOS	GRADE	AMOS	AMOS	MCC	EXP	UR	SEX
0802	03	0402	0000	MC4	1	1	M

Figure 1.2 Officer Inventory.

similar descriptions that specify the requirements for the officer filling the billet. The relative priority in which billets should be filled is also specified. Using the information from the Dictionary, the adjusted Inventory and the adjusted ASR, the OSGM then finds the best fill and fit possible. The method in which the current OSGM derives the staffing goal will not be discussed.

#### B. CURRENT ISSUES

There are many issues today that impact the Marine Corps and the way in which it assigns its officers to billets. One of the most obvious to the military itself is the rising cost of PCS (Permanent Change of Station) moves. In this type of move the officer and his/her family are moved from one duty station to another. Increased cost and Congressional limits on PCS funds have impacted all of the services. One such impact is the delay of orders that have already been issued. Another impact of increased PCS costs is the possibility of increased tour lengths. Current Marine Corps stateside tours are 36 months long. These could be increased to 48 months in order to decrease the number of yearly moves. Another issue now facing all of the services is that of joint tours. A joint tour is where a member of one Armed Service is stationed with another of the Armed Services. It is intended that this type of tour will improve inter-service operability. These billets must be established in each of the services with compensatory reductions elsewhere in each branch. These billets must also be handled by the monitors and therefore included in the OSGM. With increased public awareness of the cost of the military has come an increased interest on the part of Congress in the internal workings of each of the services (in some circles this is known as micromanagement). Because of this, the Marine Corps must be able to, even more than before, judge the impact of any proposed personnel policies before they are implemented. A much dreaded thing in each of the services is manpower cuts. There

have already been some and will probably be more. The Marine Corps must be able to gauge the impact of these cuts in order to see what changes to make in order to maintain operational readiness. Finally, the current OSGM has essentially reached its maximum capability. It does not have the ability at this time to adequately handle any of the issues just mentioned. It could be improved, but the expense would far outweigh the benefits.

### C. PURPOSE

This thesis will provide MMOA-3 with a prototype design for an allocation model. The design is not a smooth, production design because it does not attempt to provide a final, fixed form of solution. Instead, it gives the user, MMOA-3, a flexible solver system that can be modified with relative ease. This will allow the users to develop the specifications for a new system with great confidence that the new system, based on the modified prototype model, will satisfy their requirements.

### D. THESIS ORGANIZATION

The thesis will be organized in the following manner. The user requirements will be defined in the terms used by the user. A statistical analysis will be presented with any impacts the results have on any of the user requirements. The proposed design will be detailed both at the system level and at the detailed design level. Following the design will be a discussion of some of the major requirements and how the design answers those requirements. Next, the prototype used to validate the design will be presented and an analysis of the results of the prototype given. Finally, the conclusions and recommendations derived during the development of the model will be discussed. A glossary of terms is provided in Appendix A.

## **II. USER REQUIREMENTS**

The user requirements for the prototype were developed over a period of several months. The problem was initially introduced during a week long visit to MMOA-3 at HQMC in Washington, DC. Each of the staff at MMOA-3 was interviewed, as well as some of the monitors and personnel department heads. An initial problem statement was drafted and then presented to Major Hundley of MMOA-3 for review while at HQMC. During the following three months, the problem statement was further refined and again reviewed by Major Hundley three more times. The resulting user requirements are presented below.

### **A. COMPUTER**

One of the first requirements of the prototype model is that it be capable of being run on the Marine Corps mainframe at Quantico, VA. Currently, the OSGM is maintained on a contractor's mainframe in Maryland. A detailed procedure must be followed to transfer all of the working data files to the contractor's mainframe so that a model run may be done. Since MMOA has terminals to the Quantico mainframe, having the prototype on the mainframe would allow easy access for running or modifying the prototype. Also, the cost for maintaining the system would be much less.

### **B. WINDOW SIZE**

Another requirement for the prototype model is that it have a variable 'window' size. One of the preparations that MMOA makes when it wants to run the OSGM is to produce the latest inventory of officers. This is a listing of all Marine Corps officers that have at least one year of active duty service remaining. The date on which the program that produces the inventory of officers is run is called the staffing goal date. The 'window' is a period of time, beginning on the staffing goal date. Any officers whose current tours of duty end any time within the window are eligible to move and are called 'movers'. The movers are the officers that will be assigned to new billets by the monitors. Any officers whose tours of duty end before or after the window are not eligible to move and are called 'non-movers'. In the current OSGM the window is

fixed at one year. However, the desire is to have a variable window size. For example, the window could be as small as one month or as large as three or four years. If the window were one month, the set of movers would be very small, while the set of nonmovers would be very large. If the window were over three years, essentially the entire officer corps would be classified as movers.

### C. COST FACTORS

A third requirement for the prototype design is that it incorporate various 'cost factors'. In the current OSGM, there are two measures of effectiveness used to gauge the performance of a model run. The first is the number of billets that are filled by the model. Obviously, if the model fills a low percentage of billets, the results will not be very useful. Even though the measure is expressed in the number of people, it is usually referred to as a percentage of the officers allocated. The other measure of effectiveness is the average, over the entire population of officers, of how well each officer matches or 'fits' the billet he is allocated to. As mentioned previously, in a normal run not all of the billets can be filled and the degree of fit is usually not the maximum. There must, then, be a tradeoff between the two. Another factor that can be used to gauge the performance of a model run is a total PCS cost. This factor is not supported on the current OSGM. It is, however, an important piece of information when considering budget cuts and congressional inquiries. The total PCS cost for a model run is calculated by summing up the estimated PCS cost for each mover. This estimate is based on the mover's current command location and the location of his/her allocated command that he/she may move to. The estimate may be continually refined by updating the data from (recent) historical records. The PCS cost may just 'tag along' as an extra piece of data in the model solution and be summed up after the solution or it may be used as a criteria by the solver routine when matching officers to billets. A listing of the cost factors and their descriptions are given in Figure 2.1 .

### D. CRITERIA

There are currently seven criteria used to describe each officer in the inventory and each billet listed in the ASR. The criteria are: primary MOS (PMOS), grade, two additional MOS's (AMOS), an experience marker, a use restriction marker that indicates whether the person/billet is an unrestricted officer/billet or an Limited Duty Officer (LDO) officer/billet, and a sex marker. Figure 2.2 shows the criteria with

FACTOR	DESCRIPTION
Fill	Actual number of billets filled
Fit	1 : Best fit 5 : Worst fit
PCS	\$0 : Nonmover \$0 - Max : Mover

Figure 2.1 Cost Factors.

examples of each. All of these must have a valid value and are used in matching the officers to billets. The final requirement is that the prototype design facilitate new criteria being added and used in the matching process, also that the design allow the optional removal of one or more criteria from consideration for matching on any given model run. An example of a new criteria that might be incorporated in the model is a joint MOS (JMOS) designator given to officers who qualify for joint tours and to billets that require an officer with such a designator. It is also possible for experience, use restriction or sex markers to be selectively removed from consideration so that the impact they play on the matching of officers to billets could be studied. The same type of logic could be applied to any new criteria that are added at a later date.

CRITERIA	EXAMPLE
PMOS	0802 - Artillery, 0302 - Infantry
Grade	O2 - Lieutenant, O3 - Captain
AMOS	9646 - Computer Science, 0402 - Logistics
Use Restriction	1 - LDO, 2 - Unrestricted
Experience	0 - No experience, 1 - Experience
Sex	M - Male, F - Female

Figure 2.2 Matching Criteria.

## **E. MISCELLANEOUS**

Although no formal time constraints were given for the model run time, MMOA desired that the prototype be as efficient as possible. It is anticipated that the prototype may be run frequently as new aspects of the allocation problem are modeled using the prototype. A desire (that was not given as a requirement) was that the prototype use the data currently used by the OSGM as input, in the same format, so that duplicate forms of data would not have to be maintained.

### **III. DATA ANALYSIS**

#### **A. SCOPE**

The statistical analysis presented here is a simple study of the personnel and billet data, intended to discover the character and properties of the data. It is not intended to be a detailed, complex analysis checking for correlations between data elements, etc. The knowledge derived through this analysis enhances the understanding of the problem and permits greater insight into possible solutions.

#### **B. ANALYSIS**

The analysis will cover several different data sets, all of which are directly used in the allocation problem. First, a breakdown of different attributes of the inventory of officers will be shown, then the division of officers among grades. The various sources of billets will be given, followed by a listing of the number of billets assigned to each staffing precedence level (SPL). The next two tables show the breakdown of the E1 and E2 'cards' from the dictionary. Finally, the number of officers in each of the officer type categories will be presented.

##### **1. Inventory**

Within the inventory of officers, several different groupings occur. The ones shown in Table 1 are by MOS, use restriction, experience and sex. Just over half of the officers in the Marine Corps have only a PMOS. Fewer still have one AMOS and two AMOS's. An analysis presented later will show how many types of billets require no, one, or two AMOS's. This is important because those officers with one or two AMOS's are qualified to fill billets that do not ask for an AMOS, and if pulled to fill such billets may leave other, more specialized billets vacant. The Limited Duty Officers constitute a small percentage of the officer corps and should, therefore, represent a small part of the entire allocation problem. Over half of the officers are designated to be experienced. Whether or not an officer is considered to be experienced depends on his/her rank, number of years in their MOS, and other factors. Finally, the male/female split is given.

##### **2. Grade**

As can be seen in Table 2, the greatest bulk (over half) of the officer corps are Lieutenants and Captains. This follows directly from the pyramid-shaped organization

**TABLE 1**  
**INVENTORY**

Total Officers on Active Duty	20050	
Officers with PMOS only	11543	57.5%
Officers with PMOS, one AMOS	4986	24.9
Officers with PMOS, two AMOS	3521	17.6
-----		
Unrestricted Officers	18785	93.7%
Limited Duty Officers	1265	6.3
-----		
Officers with Experience	11290	56.3%
Officers with no Experience	8760	43.7
-----		
Male Officers	19392	96.7%
Female Officers	658	3.3%

of the Marine Corps. The Warrant Officers serve in specialized billets, for the most part, and are all prior enlisted. The general officers are not presented in this data because they are not included in the allocation model. They are 'monitored' by the Commandant of the Marine Corps.

### 3. Billet Source

Not all of the billets filled by officers are listed in the Authorized Strength Report (ASR). As seen in Table 3, there are over three thousand training billets. The majority of these are student billets at Marine and other service commands. For example, approximately nine hundred of the billets are for Second Lieutenants at the Basic School in Quantico, VA. Others are MOS training billets at various schools.

### 4. Billet Description

The figures in Table 4 are derived from the data produced in a partial allocation model run. As seen in the next table, the lowest numbered Staffing Precedence Level (SPL) has the highest priority. The SPL is a descriptor given to every command or unit that indicates its relative priority for getting its billets filled.

**TABLE 2**  
**OFFICER GRADES**

No. of Officers		
Warrant Officer	1628	8.1%
Lieutenant	6351	31.7
Captain	6258	31.2
Major	3293	16.4
LT Colonel	1713	9.5
Colonel	807	4.1

**TABLE 3**  
**BILLETS**

Authorized Strength Report	16708
No. of Billets	
Training	3152
Nonchargeable	721

The figures shown below are a function of the data given to the model and can, therefore, be modified. One factor that greatly affects the method of solution, but is not specified anywhere in the data itself, is the fact that the billets of each SPL are filled preemptively. In other words, all of the billets of SPL 2 that can be possibly be filled are filled first. The same is done for SPL's 3, 4, and 5, in turn.

#### 5. Command Priority

Table 5 gives the breakdown of the number of E2 'cards' by SPL. The term 'card' is a holdover from the time that the data for each E2 record was actually on a punch card. The E2 records have two main functions. The first is to assign each billet or set of billets in the ASR an SPL. This can be seen in the previous table where the billets are divided by SPL. The second function is to tie each billet listed in the ASR to a set of billet descriptors (E1 cards). These are explained in the next paragraph.

TABLE 4  
SPL BILLETS

SPL 2	1149	6.9%
SPL 3	6649	40.2
SPL 4	1776	10.8
SPL 5	6973	42.1
Total	16547	100.0

TABLE 5  
E2 SPL

SPL 1 (Highest Priority)	1	0.02%
SPL 2	504	12.8
SPL 3	2567	65.1
SPL 4	84	2.1
SPL 5 (Lowest Priority)	782	19.8

As just mentioned, each billet is tied to a set of billet descriptors. These are the E1 cards. As seen in Table 6, there are up to five choices for each billet. There is a logical progression of fewer cards for each greater numbered choice. Those billets that have very stringent requirements will have fewer choices than those that will take a wide range of officers.

The officer type is a descriptor used in the E1 cards. It is used for billets that may be filled by an officer from a set of MOS's. This type of billet requires a general, rather than specific, background. Each of the officer types listed includes all grades, Warrant Officer through Colonel. As fitting a combat service, the ground and air combat officer types are the largest. Even if the figures given were reduced to reflect only a single grade, it is easily seen that any billet that specifies one or more officer types will have tens or hundreds of officers that are qualified to fill that billet. This

TABLE 6  
E1 PRIORITY

PRI 1 (1st Choice)	1019	46.3%
PRI 2	597	27.2
PRI 3	370	16.8
PRI 4	174	7.9
PRI 5 (5th Choice)	40	1.8

presents a special problem for the solution designed in this thesis, as will be seen later.  
A breakdown of the officer types given in Table 7.

TABLE 7  
OFFICER TYPES

Air/Ground Combat Support	558	3.9%
Air/Ground Service Support	555	3.9
Ground Combat	4813	33.7
Ground Combat Support	1172	8.2
Ground Combat Service Support	2806	19.6
Naval Aviator Fixed Wing	1726	12.1
Naval Aviator Helicopter	2277	15.9
Naval Aviator NFO	387	2.7
Total	14294	100.0

The data presented in this last table, Table 8, is a breakdown of the billet descriptor (E1) cards. The E1's have many 'wildcards' that allow many options for the various descriptors. As can be seen for experience, use restriction, and sex, the largest proportion of billet descriptors are those that allow either. For MOS's, the single largest category is that of the PMOS only. Relatively few billet descriptors require a PMOS and one or two AMOS. There are also billets that do not specify what PMOS

an officer must have, only that they carry a certain AMOS. There are also over four hundred billet types that ask for any officer within a large range of PMOS's. The Occupational Field and SubOccupational Field are similar to the Officer Type, but on a smaller scale. These ask for an officer in a particular MOS area; for example, an officer in the finance/disbursing MOS field.

## IV. SYSTEM DESIGN

### A. DESIGN PRINCIPLES

Through conversations with MMOA about their requirements and through the study of the data used in the allocation model, several design principles were developed. These principles were used in the development of this design. Please note that the order in which the principles are presented reflects no relative priority among them. The first principle developed is that the model should support iteration. The model will not be used just occasionally, but may be used repeatedly throughout each month. The design should allow the user to repeatedly use the model, entering the model each time at the point most appropriate for the work being done. The second principle is driven by the relatively large data sets and the amount of computation necessary during a model run. Any operation should be done on the smallest data set possible. This will reduce both the model run time and the model run cost. The third design principle is that the design should be modularized, supporting easier maintenance, and future expansion or changes. It is much easier to modify a small module, rather than a large, monolithic one. There is a trade-off here in that the larger number of modules requires that some data be written to and read from files in order to pass the data from module to module. For the purposes of this prototype, however, the cost is acceptable. The last design principle is one that is hard to completely specify and that is flexibility. The word is overused and often misunderstood. In this particular instance, flexibility means the capability to use different officer and billet descriptors for matching purposes on various model runs with only a few minor code modifications. This includes the ability to add new, currently unknown descriptors to the model in the future. The entire design presented here emphasizes the functions of each module. The module interdependencies are simple and straightforward. Block diagrams of each level of the design and the system design are given in Figures 4.1 through 4.3, and Figure 4.4, respectively.

### B. HIGH LEVEL

The high level design provides the model the ability to be selectively iterated. There are three major modules in the design. The first is the initial inventory preparation. All inter-module communications are accomplished using files--data files.

The second is the data preparation and matching module. The third and final is the solution and report generation module. The modules are presented in the order of execution. The initial inventory preparation module converts and compresses necessary data into formats usable by the prototype and eliminates all data no longer needed by the model. This reduces the amount of unnecessary processing. It also generates some reference data files that are used by the other modules. The data preparation and matching module allows the user to specify which officer/billet descriptors will be used in matching officers to billets, and then performs the matching. Once the first module has been run, the second module may be run and rerun many times, without having to reexecute the first module again. The output of the second module is a listing of all possible matches of officers to billets. The solution and report generation module takes this data, prepares it for the solver, solves the allocation problem and then generates the requested reports.

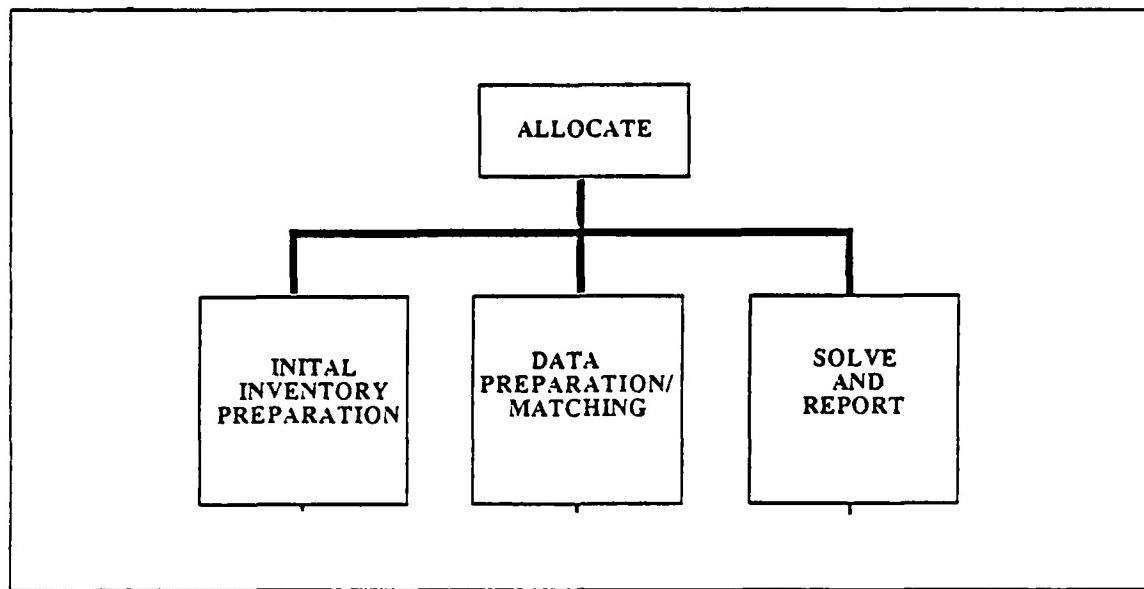

Figure 4.1 High Level Design.

### C. MID LEVEL

The mid level design implements the modularization. The initial inventory preparation module is made up of two submodules. The first, using the staffing goal date and window provided by the user, splits the inventory of officers into movers and

nonmovers. Because of the nature of the data, the nonmovers are not set aside as might be imagined. In order to improve the quality of the solution, the nonmovers are matched to billets just like the movers are with one exception. The nonmovers are eligible to be matched only to billets in the command they are currently serving in. After the inventory is split, the second submodule removes any officers currently in training or nonchargeable billets from the inventory. This is because the primary function of the prototype is to fill the ASR billets. The mover inventory and the reduced nonmover inventory is now available to be used by the second major module.

The data preparation and matching module is made up of three submodules. The first submodule prompts the user for which officer/billet descriptors he wishes to use. It presents the criteria currently used for use or discard. It then allows the user to specify new criteria that have been added to the model. It then creates a file with indicators for each of these descriptors. This is an optional module in that it need not be executed every time the prototype is run. It is only run when the criteria used for matching are to be changed. It applies these descriptor indicators to the inventories in preparation for the matching. The second submodule uses the same file and applies the same indicators to the billet data. The third submodule takes the inventories from the first submodule and the billet data from the second submodule and merges the two, matching each officer to every billet he/she is qualified to fill.

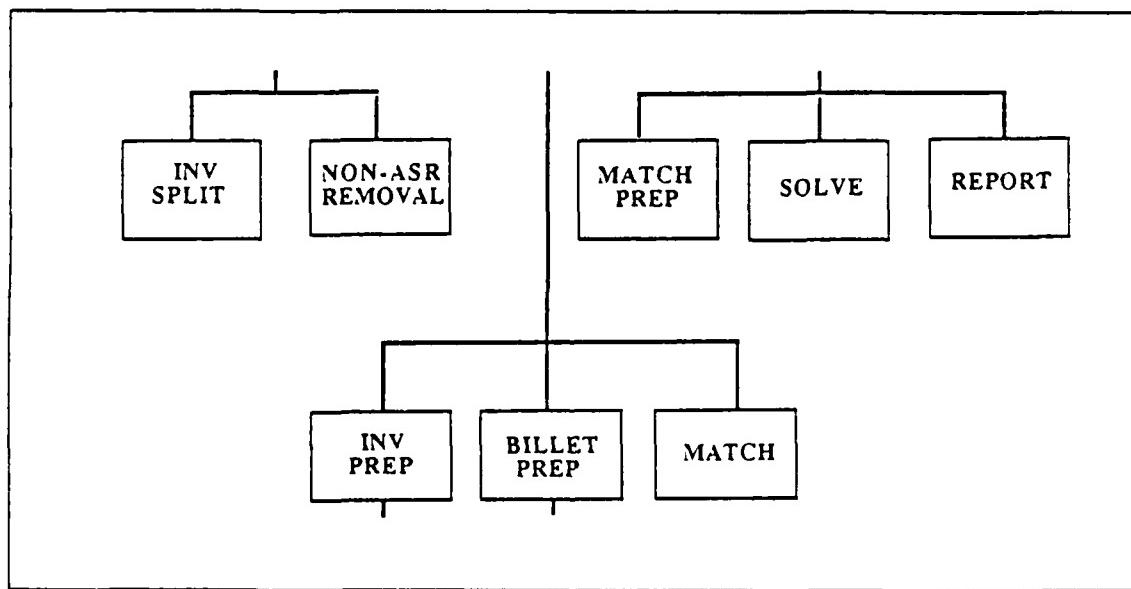

Figure 4.2 Mid Level Design.

The third major module contains two submodules. The first takes the file of matched officers and billets, puts it in a form that can be processed by the solver, uses the data from the match file to generate costs that will be for the solver and then generates an optimal solution. The second module is the report module that generates reports from the data produced by the solver.

#### D. LOW LEVEL

There are four low level modules. Two of the four support the inventory preparation submodule and the other two support the billet preparation submodule. The first module applies the grouping criteria decided upon by the user to the inventory of 'mover' officers. There are currently three standard criteria that the user can use to group the officers and billets. They are the experience, use restriction and sex of the officer or billet. If only these three were ever used , then the logic could be 'hardwired'. However, the user requirements specify that the design be able to facilitate these three, or more, or fewer. This is done by allowing any number of criteria to be used (within reason!). The combinations of criteria are then determined. All of this data is then abstracted into an ordered set of indices. This is the key to the flexibility. When the matching module is making matches, it is checking a criteria number and not an officer's experience, sex, etc. This design allows as few criteria as one, or as many as the user desires. At the same time, the module also classifies each officer as to how many AMOS's he/she has. This classification becomes very useful in the matching routine because it eliminates much unnecessary checking of officers that may have the correct criteria index but do not have the correct number of MOS's. The PMOS and/or AMOS's must still be checked to see if they match the billet descriptor, but no needless checking is done. The same procedure is applied to the inventory of 'nonmover' officers.

A similar principle to the inventory grouping is applied to the grouping of the billet descriptors. However, it is a little more complicated because the billet descriptors usually allow one additional choice for each criteria. That extra choice is an 'either'. In other words, a billet may require a male officer, require a female officer or allow either a male or female to fill the billet. The billet descriptor grouping is, therefore, a superset of the inventory grouping. To connect the two, a mapping is created from the inventory grouping into the billet descriptor grouping. This mapping is used in the matching module.

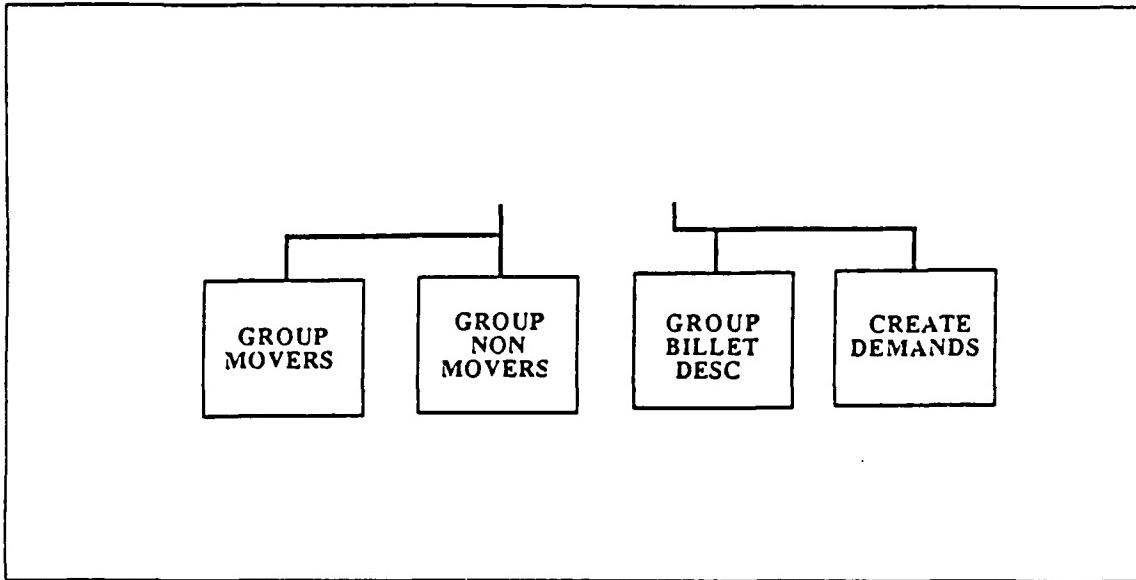

Figure 4.3 Low Level Design.

The final low level module is the module that generates the demands. A demand is a record that contains one billet descriptor, one priority level, one staffing precedence level (SPL), and one command code (MCC). Since every distinct billet type can have up to five billet descriptors, priorities one to five, each billet type can have up to five demands. There is one caveat to this. A single billet descriptor may specify more than one grade. If it does so, when the billet descriptor is expanded to one grade per line, the billet will have more than five demands. Although there are more demands than there are officers, this presents no problem. The demands are used to generate potential matches. The solver looks at all the potential matches and then selects only as many as are needed to fill the billets.

## E. SOLVER

The design and function of the solver drives the design of the rest of the system. This is because the solver is the core of the system. All of the processing prior to the model is done to prepare the data for the solver. The report generator takes the results of the solver as its input. The model developed for this system is a derivative of a network assignment model developed by Capt. Phil Exner, USMC [Ref. 1]. Capt. Exner designed the model as the centerpiece of his thesis. His model is a multiobjective optimization built on a capacitated transshipment network model and is an application of work done by D. Klingman [Refs. 2,3] and R. Rosenthal [Ref. 4]. The solver is a

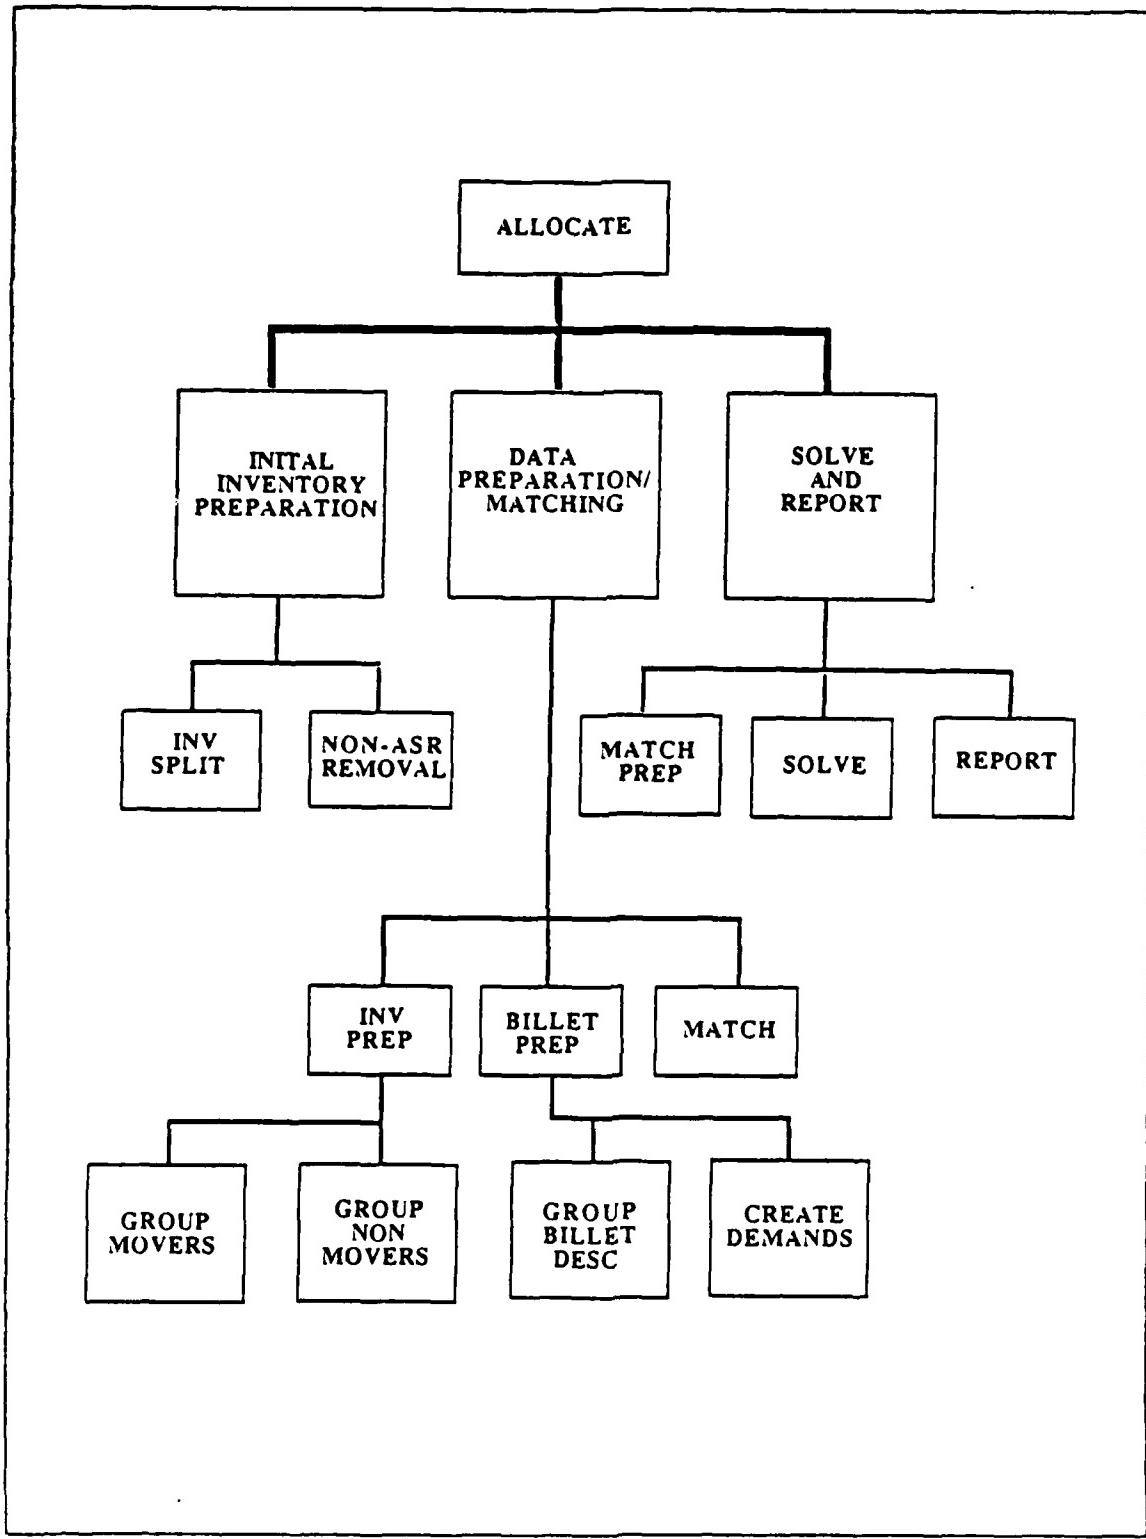

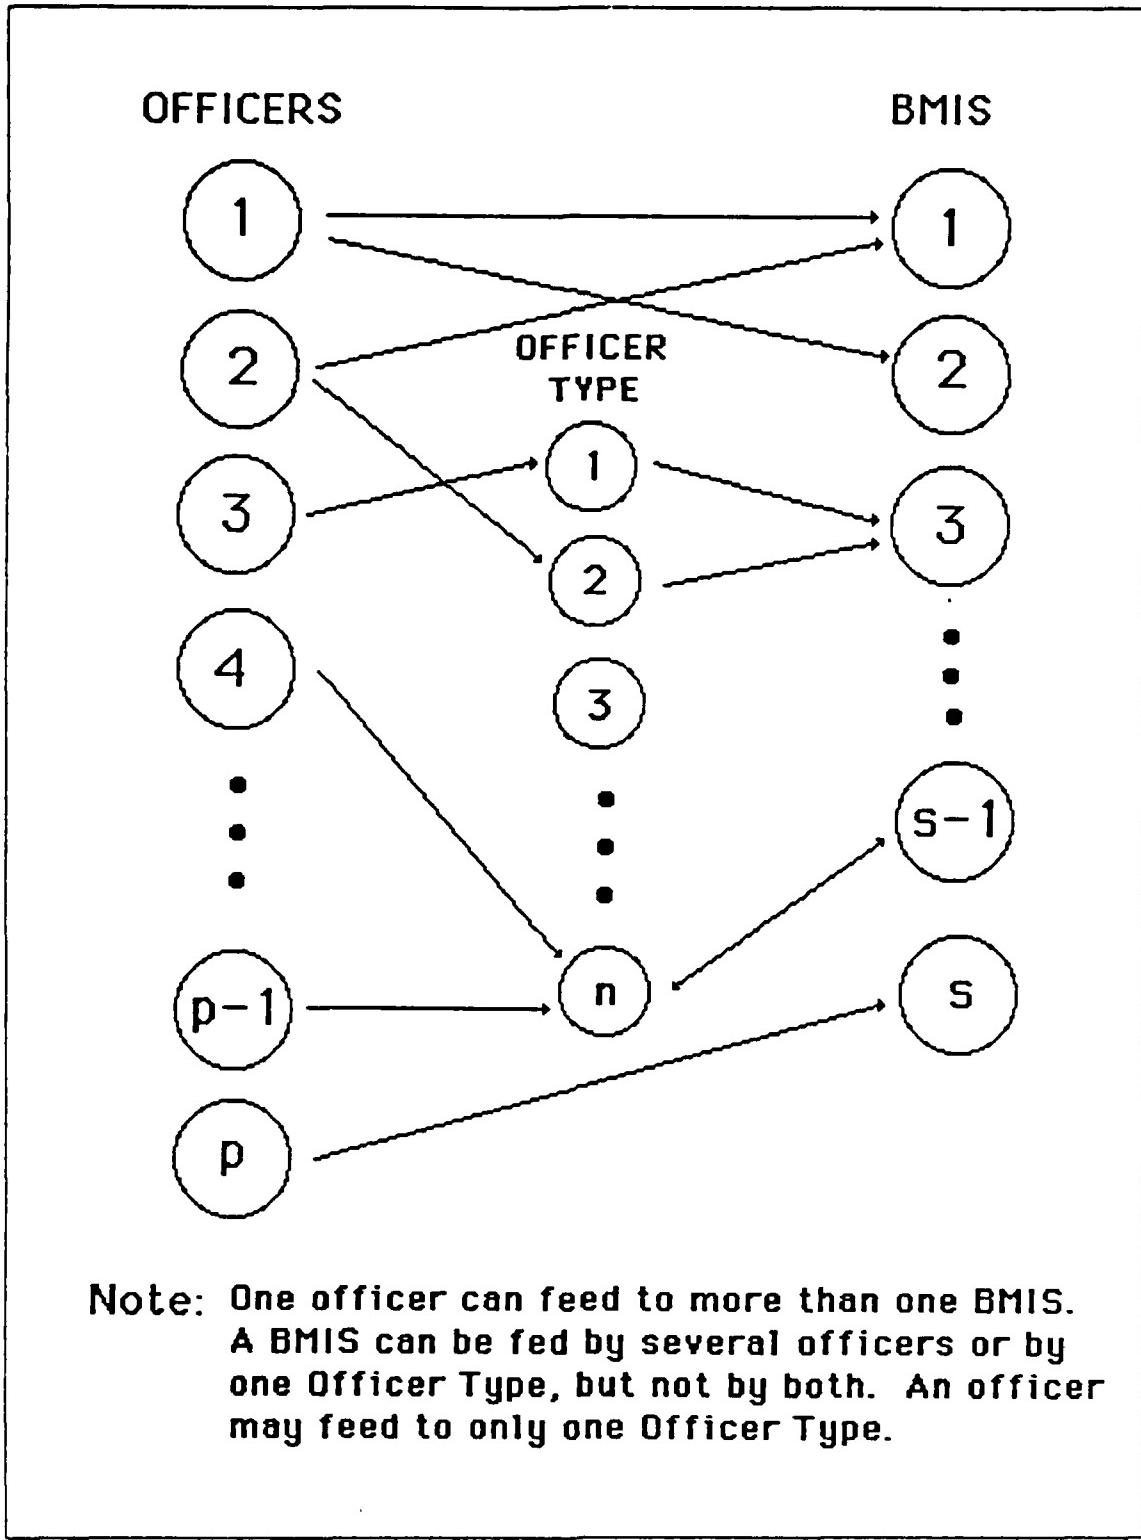

Figure 4.4 System Design.

variant of GNET [Ref. 5]. The mathematical basis for the model will not be discussed. If further information in this area is desired, please see the references.

The concept of the solver, despite all of its complicated background, is fairly simple. It essentially matches producers of a commodity to users of the same commodity. The diagram in Figure 4.5 helps to illustrate. The commodity for the model is people - officers. Each person is a producer or source. Each billet is a 'user' of an officer, needing one officer to fill it. In the diagram, the officers are listed on the left. Each officer has a specific set of descriptors (PMOS, grade, experience, etc.). The billets are listed on the right. In this case, each circle is not just one billet, but may represent several billets (BMIS), each of which is at the same command and requires the same set of officer attributes. The officer type circles (or 'nodes' as they are called in the network) are both users and sources. They act as channels to funnel hundreds of officers whose PMOS is in an officer type to the billets that request officers by officer type. Again, each officer is connected to every billet he/she is qualified for. Each 'connection' is known as an 'arc' in the network. Each arc has an associated cost. Normally this is a combination of the fit and PCS costs. Obviously, the officer with the lowest fit number (the best fit) and the lowest PCS cost would be the best choice for a billet. The solver takes all these nodes and arcs as data, along with the associated costs as input. It then fills as many billets as possible, with the lowest aggregate cost possible. The result is a one-to-one mapping, with each officer being allocated to only one billet, and each billet having only one officer. It is very possible, even likely, however, that some billets will not be filled and some officers not allocated. This is not the fault of the solver but is an artifact of the problem and data. It should also be noted that if the model is run using officer types the PCS costs will only be an estimate because any officers that are matched to a billet via an officer type have no direct PCS cost basis and can only use an average PCS cost. However, if the model is run without using officer types, the PCS cost will be as accurate as the costing data provided.

There is a difference between this model and the one developed by Capt. Exner. The model presented here solves the problem in a hierarchical fashion, filling as many billets as possible and then within that constraint finding a solution with the smallest aggregate cost. Because of this, solving for the smallest PCS cost will not reduce the number of billets filled. Capt. Exner's solver, on the other hand, is constructed in a way that allows the user to reduce any cost factor in order to improve the performance of another. In that case, the number of billets filled could be reduced to improve the fit or total PCS cost.

**Note:** One officer can feed to more than one BMIS.  
 A BMIS can be fed by several officers or by one Officer Type, but not by both. An officer may feed to only one Officer Type.

Figure 4.5 Logical Structure of the Model.

## **F. REQUIREMENTS AND DESIGN RESPONSE**

The user requirements for the system were outlined in Chapter II. A brief description of the system design was presented in Chapter IV. The following is a demonstration of how the design met the requirements set out by the users.

### **1. Computer**

The requirement that the prototype be capable of running on Marine Corps computer assets was easily met. A review of the software available on the mainframes at Quantico, VA and here at the Naval Postgraduate School revealed two common software packages: a Fortran-77 compiler and a SAS package. Therefore, the limited prototype developed as a part of this thesis to validate the design given in the thesis was written primarily in Fortran-77. All of the sorting routines and one or two other miscellaneous routines were written in SAS. This will be discussed in more detail in Chapter VI.

### **2. Window Size**

As with the first requirement, the requirement for the prototype model to have a variable window size was easily met. The design includes a module in the preprocessing section that allows the user to input the staffing goal date (in YYMM form) and the window size in months. It then uses an algorithm provided in the OSGM manual [Ref. 6] for determining if an officer is a mover or not. Since the window size is adjustable and drives the relative percentages of the mover and nonmovers, the mover and nonmover data files are variable in size. This variability in data set sizes is supported throughout the entire design.

### **3. Cost Factors**

The requirement for the design to incorporate various cost factors, some of which are unknown at this time, is accomplished in two ways. First, the calculation of the cost from the data provided is limited to a single module. Since the details of future cost factors is unknown, this limits the scope of the work necessary to incorporate the new cost algorithms. Second, the ability to 'carry' data through modules that do not affect the data is made straightforward. The logical procession of data and data transformations is easy to follow. As mentioned in Chapter Three, there are two cost factors currently used as measures of effectiveness for the OSGM: fill and fit. Fill is derived after the allocation solution has been obtained. Fit is a cost input to the solver, as is PCS cost. The design provides the framework for calculating PCS cost from the mover's current and future command locations. Any new cost factors that

can be derived directly from currently provided data can be computed in the arc generation module. New data added to the model to provide a new cost factor must be added to the inventory of officers. It may also be added to the billet descriptor and matching data if also used to determine billet eligibility. This type of change will require the most modification.

#### 4. Criteria

As just mentioned above, if any new data is added as a new criteria, it must be added to the officer inventory, billet descriptors and matching criteria. The design was developed to favor the addition of simple criteria with a 'yes-no' applications such as experienced or inexperienced. This type of criteria may be added to the grouping procedure with the least amount of modification. Only the data and modules up to the grouping modules might need minor modification. All of the modules after the grouping would be unaffected.

If a new criteria can not be reasonably added in the grouping module, the new data would have to be carried through the model up to the matching modules. The methodology for matching often will be fairly uniform, allowing straightforward modifications. This type of criteria addition, obviously, is the most difficult.

Another feature provided by the design is the ability to use a subset of the grouping criteria. For example, if it is desired to determine the effect of using versus not using experience as a matching factor, it could be done. The user has the ability to choose or disallow any grouping criteria already implemented. This is done without any code modification at all. Once the user has selected his subset of grouping criteria, the model reconfigures itself as it works through the modules. This level of abstraction can be extended to cover any new criteria added to the system.

## **V. DISCUSSION OF PROTOTYPE**

### **A. SCOPE**

A limited prototype of the design was implemented in order to validate the design concepts and provide a working model for the user. The prototype is considered limited because it does not implement every feature of the current OSGM and does not implement every feature of the design to its fullest extent. One factor affecting this was time constraints. It was not possible in the time allotted for the thesis to develop the design and produce a full implementation of the design. However, the major factor affecting the development of the prototype was the desire of the user to have a working model that could be easily modified. In this regard, the prototype can be looked at as a structure or framework that provides the basic functions necessary to develop a solution. These basic functions can then be modified or rearranged to provide a new configuration. Listings of the programs in the prototype are given in the Appendices.

### **B. DISCUSSION**

The prototype was developed in three parts in order to support the designed ability to selectively iterate through the model. The three parts are the initial preprocessing stage, the intermediate processing stage and the final or solution stage. The user can enter the prototype at the beginning of any of these three stages. The initial preprocessing stage is designed to be run every time a new inventory of officers is developed which is normally once a month.

#### **1. Initial Stage**

In this first stage, three MOS reference files are created. Then the officer inventory is split according to the staffing goal date and window size. The nonmover inventory is then reduced by removing those officers in the training billets listed in the Dictionary. The resulting mover, nonmover and reference files are now available to be used as often as desired.

#### **2. Intermediate Stage**

The intermediate processing stage performs the groupings and matches. It first allows the user to choose from the grouping criteria already provided by the prototype or to add new criteria whose values have been added to the inventory and billet data files. The groups are made by taking the cross product of the choices of the criteria chosen.

It can be seen in the example in Figure 5.1 that if a large number of criteria are used or several criteria with a large number of choices, the number of groups will grow exponentially and no benefit will be gained by the grouping. In fact, the prototype performance could be worsened. The larger the number of groups, the fewer the officers or billets that will be in any one group and the more processing that will be required. Therefore, a balance must be maintained. It is estimated that performance will decrease rapidly as the number of groups approach and exceed one hundred. This grouping is applied to both the movers and nonmovers. A superset of the grouping is also applied to the E1 (billet) data.

	USR	EXP	SEX
	UNR LDO	Y N	M F
GROUP	USR	EXP	SEX
1	UNR	Y	M
2	UNR	Y	F
3	UNR	N	M
4	UNR	N	F
5	LDO	Y	M
6	LDO	Y	F
7	LDO	N	M
8	LDO	N	F

Figure 5.1 Sample Grouping.

Next, the ASR is expanded, adjusted, numbered and split into BMIS sets (E2 cards). A BMIS set is a set of billets at the same command, with the same SPL and monitor, that have the same set of billet descriptors. Each BMIS number has associated with it the number of billets needed to be filled for that BMIS. The BMIS sets are then split by SPL and merged with the billet descriptors (E1 cards) to make the billet demands. Finally, the movers and nonmovers are merged with the billet demands to create the matches. The match files contain the inventory number of the officer, the BMIS number of the billet and the cost data needed to calculate the cost of the match for every match in the file.

### **3. Final Stage**

The final or solution stage uses the match files to create the arcs needed by the GNET solver and then solves the matches for each SPL in turn. The solution can be developed in this way because the SPL's are preemptive. The problem could not be partitioned by MOS or grade as it is by SPL because the billet descriptors allow MOS and grade substitutions. This means that there are no clear cut divisions of the problem by MOS or grade.

The first SPL solved for is SPL0 which covers all of the nonchargeable billets. The nonchargeable billets are filled first so that a truly representative inventory can be used to fill the authorized billets from the ASR. After this, SPL's 1 through 5 are filled, in sequence. After each SPL, the remaining matches in the match files are reduced by removing those officers allocated to higher SPL billets. This reduces the problem size for each subsequent SPL and provides a better performance.

The other program in the final stage uses the solution developed by the GNET solver and accesses the inventory and billet files to produce reports. It needs to access the inventory and billet files because all the solver gives in the solution is the inventory number and the BMIS number. This last program provides only the essential tools for making the reports and does not attempt to generate all of the currently used reports. It would be possible to restructure this program to put the solution data in a form usable by a database package. This would allow ad hoc queries by the user. Discuss some of the specifics of the prototype and how these meet the design specifications.

## **C. ANALYSIS OF RESULTS**

The actual and estimated performance times for the prototype implementation are given in Tables 9, 10 and 11. Using the standard one year window size, the officer population was divided into 7,251 movers and 13,815 nonmovers. It should be noted here that SAS was used only for the sorting of the data sets. Fortran was used in all of the actual data conversion and matching. Using PULLE3T FORTRAN, 427 nonmover officers that were in training billets were removed from the nonmover inventory. The remaining training billets and all of the nonchargeable billets will be filled during the SPL0 run of the solver. Operating on the two parts of the officer inventory in the intermediate processing stage produced better performance times than operating on the inventory as a whole. The majority of the intermediate stage

programs are for billet data preparation. The match files produced by the two MATCH programs were reduced in size because the officer type billet descriptors were not included in the processing. This allowed a significant time savings in the processing time. A time estimate for using the solver iteratively on the separate SPL match files produced better results than the projections solving of the entire problem as one large problem. The decision to solve the problem by SPL's was motivated by a recommendation given in Capt. Exner's thesis [Ref. 1].

## **VI. CONCLUSIONS AND RECOMMENDATIONS**

### **A. CONCLUSIONS**

There were several conclusions drawn from the results of the design and from the work performed in developing and verifying the design. The first is that the design is a viable one and does provide the flexibility and expandability requested by the user. The design is sufficiently robust to allow future enhancements and modifications with relative ease. Another conclusion is that the allocation problem can be broken down into smaller sub-problems and each of them solved individually. Due to the nature of the solver, the total time of solving the smaller problems can be significantly less than the time to solve the entire problem as a whole. Along this same line, it is also true that smaller, more specialized allocation problems can be easily set up to be solved. For example, if a special scenario were established that only required a small composite group of Marines, only the officer inventory and billet descriptor data files would have to be changed in order to run the problem through the model. Another conclusion that was recognized early in the development of the design was that the solution method could be generalized for more than just military applications. Many commercial companies have similar personnel and job requirements. Any criteria that can be quantified can be used as matching criteria. This would allow the companies great flexibility in establishing job requirements. The final conclusion was that the current method of billet description can be simplified. The major problem lies in the method of PMOS specification. Most of the billets specify a single PMOS for each choice. Some, however, specify a range of allowable PMOS's by using occupational fields, suboccupational fields or officer types. Figure 6.1 gives a sample of the number of officers in an occupational field and officer type for the grades specified. Each of these officers would be listed once for every billet they are eligible for. It is not reasonable, with the type of solver used in the prototype, to list this many officers for every billet that calls for an occupational field or officer type. A much smaller set of eligible officers would still allow a good solution.

### **B. RECOMMENDATIONS**

Based on the conclusions presented above, these are some recommendations for future improvements to the officer allocation problem as it relates to this model. The

OCC FIELD	GRADE	NR OF OFFICERS
30xx	O3	363
OT	GRADE	NR OF OFFICERS
GDCB	O2	1155

Figure 6.1 PMOS Specifications.

first is that the results generated by the prototype be evaluated and traced in order to see which of the billet division records (E2) and the billet descriptors (E1) were actually used in the development of the solution or to what degree they were used. It is possible that due to the nature of the solver used in the prototype that the billet data may be able to be condensed. For example, it may be found that some of the third, fourth, and fifth choice billet descriptors never get used in the generation of the solution. These could be removed, and reduce the processing time and the data file size. Following this same line of thought, it would be possible to simplify the billet descriptors, PMOS descriptors in particular, if a reduction of the scope of the PMOS descriptors were done. For example, the occupational field 30xx might be replaced by 307x, which has only 27 Captains (O3's). This kind of specification would allow the monitors to be more exact in billet requirements while not losing any ability to fill all of their billets because the prototype solver inherently uses a wider officer population base than the current solver. Another recommendation would be to put the results of a model run in a database, with the data divided between the monitors. This would allow the monitors to make ad hoc queries of the data with the results of the query in any form they wished. A final recommendation is that a good PCS cost basis be developed. The prototype allows the calculation and summation of PCS costs for a model run. Updating and maintaining the PCS cost factors would allow greater confidence and better planning based on the PCS costs generated during a model run. Additional information could easily be added to the personnel data file for use in the PCS cost calculation. This data would be the number of dependents in each age group that receives different moving allowances.

## APPENDIX A

### GLOSSARY OF TERMS

AMOS	Additional MOS - a subspecialty (MOS) that an officer may have.
ASR	Authorized Strength Report - a listing of all authorized officer billets.
BMIS	a set of one or more billets with the same command, billet descriptor, SPL, billet MOS and billet grade.
BMOS	Billet MOS - recommended MOS of the officer who will fill the specified billet.
DICTIONARY	a collection of files used by the model in modifying the Inventory, ASR and making the allocations for the staffing goals.
EXCESS	a nonmover who cannot fill any ASR billet within his MCC.
FILL	number of billets, for a model run, that have personnel allocated to them.
FIT	how well the officer type allocated to a billet matches the stated requirements for that billet.
FIXED	a person whose tour does not end in the window and therefore is not considered for a billet outside of his MCC for the model run. The same as NONMOVER.
FREE	a person whose tour ends in the window. The person is free to be allocated to any billet at any MCC that he qualifies for. The same as MOVER.
GRADE	the rank of an officer.
INVENTORY	a current listing of the Marine Corps officer population.
MAC	Monitor Activity Code - identifies the monitor who is responsible for the data associated with the MAC.
MCC	Monitored Command Code - a code that specifies the command under which a Marine is serving.
MMOA	Manpower Management Officer Assignment Branch - the office in HQMC responsible for assigning officers to billets.
MONITOR	officer in MMOA responsible for filling all the authorized billets for a given set of MOS's and grades.
MOS	Military Occupational Specialty - Ex: Infantry, Artillery, Tanks, etc.

NON-CHARGEABLE	a person who is either a prisoner, patient, transient or in training (P2T2).
OFFICER TYPE	1) A group of officers with the same PMOS, Grade, experience, etc. 2) A code that represents a specific set of MOS's.
OSGM	Officer Staffing Goal Model - a computer program that takes an Inventory, ASR and Dictionary as input and returns an allocation of the officers to the billets.
PMOS	Primary MOS - the specialty that an officer will devote most of his/her career to.
PRIORITY	the relative importance of a billet descriptor for use in filling a billet. (PRIORITY = 1-5)
SPL	Staffing Precedence Level - a number reflecting the relative importance a command holds for filling its billets. (SPL = 1-5)
STAFFING GOAL DATE	the reference date on which a model run is based. It is the date the current officer inventory is produced.
WINDOW	the number of months before the run date in which all personnel whose current tours end are considered free.

## APPENDIX B

### PROTOTYPE PROGRAM REVIEW

#### PREPROCESSING:

NUMMOS FORTRAN      NUMBERS THE PRIMARY AND ADDITIONAL MOS's IN THE B1 FILE FOR USE IN LATER PROGRAMS.  
PERFORMANCE - 0.40 SEC

INVSPL FORTRAN      BREAKS THE ORIGINAL INVENTORY INTO MOVERS AND NONMOVERS, ACCORDING TO THE STAFF DATE AND WINDOW SIZE.  
PERFORMANCE: 58.33 SEC

BSORT SAS      SORTS THE NONMOVER INV FILE BY MCC, PMOS, GD.  
PERFORMANCE - 18.58 SEC

EXPE3 FORTRAN      EXPANDS THE E3 CARDS INTO A SINGLE LINE FORMAT.  
PERFORMANCE - 0.63 SEC

E3SORT SAS      SORT THE EXPANDED E3 CARDS BY CAT, MOS, GD.  
PERFORMANCE - 0.62 SEC

DIVE3 FORTRAN      DIVIDES THE E3 CARDS INTO TRAINING AND NONCHARGEABLE AND CONVERTS THE GRADE AND MOS.  
PERFORMANCE - 0.87 SEC

PULLE3T FORTRAN      REMOVES ANY PERSONNEL AT ANY F3 MCC E3T FILE.  
PERFORMANCE - 26.24 SEC

#### INTERMEDIATE PROCESSING:

MKCRIT FORTRAN      ALLOWS THE USER TO DEFINE THE GROUPS HE WISHES TO USE FOR THAT PARTICULAR RUN.  
PERFORMANCE - 0.02 SEC

GRNINV FORTRAN      GROUPS THE NONMOVER INVENTORY BY THE GROUPS SPECIFIED BY MKCRIT FORTRAN.  
PERFORMANCE - 28.95 SEC

GRMINV FORTRAN      GROUPS THE MOVER INVENTORY BY THE GROUPS SPECIFIED BY MKCRIT FORTRAN.  
PERFORMANCE - 15.31 SEC

EISORT SAS      SORTS THE E1 CARDS BY BOD.  
PERFORMANCE - 3.44 SEC

EXPE1 FORTRAN	EXPANDS THE FULL E1 FILE BY ENUMERATING FROM LOGD TO HIGD. IT ALSO TRANSFORMS EXP AND UR. PERFORMANCE - 7.51 SEC
GRE1 FORTRAN	GROUPS THE E1 FILE ACCORDING TO GROUP CRIT. PERFORMANCE - 6.17 SEC
EXPASR FORTRAN	EXPANDS THE ASR FROM THE ORIGINAL FORMAT TO A SINGLE LINE FORMAT AND NUMBERS THEM. PERFORMANCE - 9.17 SEC
EXPC1 SAS	EXPANDS THE C1 CARDS FROM THE ORIGINAL FORMAT TO A SINGLE LINE FORMAT. PERFORMANCE - 0.15 SEC
ASORT SAS	SORTS EXP ASR INTO MOS GD MCC FORMAT. PERFORMANCE - 8.10 SEC
CSORT SAS	SORTS EXPC1 FILE INTO MOS GD MCC FORMAT. PERFORMANCE - 0.32 SEC
ROLLC1 FORTRAN	ROLLS UP ANY DUPLICATE C1 LINES IN THE C1 FILE. PERFORMANCE - 0.51 SEC
ADJASR FORTRAN	APPLIES THE ADJUSTMENTS GIVEN IN THE C1 CARDS TO THE ASR. PERFORMANCE - 8.62 SEC
NUMASR FORTRAN	NUMBER THE ASR AND GENERATE A POINTER ARRAY. PERFORMANCE - 9.46 SEC
E2SORT SAS	NUMBERS AND SORTS THE E2 CARDS BY MOS, GD, MCC, SPL, BOD, MAC. PERFORMANCE - 4.83 SEC
BMIS FORTRAN	IDENTIFIES AND NUMBERS EACH SEPARATE BMIS FROM THE SORTED E2 FILE. PERFORMANCE - 6.72 SEC
REND FORTRAN	BREAKS THE BMIS CARDS INTO SPL GROUPS. PERFORMANCE - 7.32 SEC
BMIX FORTRAN	MERGES THE ASR AND VALID E2 CARDS. PERFORMANCE - 24.83 SEC
MSORT SAS	SORTS THE TOTAL MIX RECORDS BY BOD. PERFORMANCE - 8.88 SEC
DEMAND FORTRAN	MERGES THE E1 CARDS AND THE MERGED TOTAL MIX CARDS INTO A DEMAND FILE. PERFORMANCE - 40.93 SEC

NMATCH FORTRAN	MATCHES THE NONMOVERS TO THE DEMANDS. PERFORMANCE - 60.00 SEC (est)
MMATCH FORTRAN	MATCHES THE MOVERS TO THE DEMANDS. PERFORMANCE - 75.00 SEC (est)
FINAL PHASE :	
SHUFFLE SAS	SORTS THE MATCH DATA BY PMOS AND BMIS FOR THE SOLVER. PERFORMANCE - 50.00 SEC (est)
SOLVE FORTRAN	GNET SOLVER THAT WILL SOLVE EACH SPL IN TURN. PERFORMANCE - 180.00 SEC (est)
REPGEN FORTRAN	USES THE SOLVER RESULTS AND OTHER FILES TO GENERATE THE VARIOUS REPORTS REQUIRED. PERFORMANCE - 90.00 SEC (est)

## APPENDIX C

### INITIAL PROCESSING PROGRAMS

#### NUMMOS FORTRAN

```
* THIS PROGRAM TAKES THE B1 CARDS AND MAKES THREE FILES
* THAT WILL BE USED TO CONVERT THE MOS'S INTO MOS
* NUMBERS. IT ALSO CREATES A FILE FOR INDICES FOR THE
* OFFICER TYPES INTO THE MOS NUMBERS.
PROGRAM NUMMOS
